1. (a) **function** SET-INTERSECTION( $X, Y$ )  
     $X' \leftarrow \text{SORT}(X)$   
     $Y' \leftarrow \text{SORT}(Y)$   
     $i \leftarrow 0$   
     $j \leftarrow 0$   
     $\text{intersection} \leftarrow \text{EMPTY-SET}$   
    **while**  $i < \text{LENGTH}(X')$  AND  $j < \text{LENGTH}(Y')$  **do**  
        **if**  $X'[i] < Y'[j]$  **then**  
             $i \leftarrow i + 1$   
        **else if**  $X'[i] = Y'[j]$  **then**  
             $\text{intersection} \leftarrow \text{INSERT}(\text{intersection}, X'[i])$   
        **else if**  $X'[i] > Y'[j]$  **then**  
             $j \leftarrow j + 1$   
        **end if**  
    **end while**  
    **return** intersection  
**end function**

Assuming we have a sort function that runs in  $O(n \lg n)$  time and an insertion function that runs in  $O(1)$  time, this algorithm should take  $O(n \lg n)$  time.

We first sort the two sets in  $O(n \lg n)$  time.

When we're iterating over the two arrays, we take a maximum of  $O(n)$  time as each iteration runs in  $O(1)$  time. This is less than  $O(n \lg n)$  time, so our upper bound has not changed.

Thus, we have an intersection algorithm that runs in  $O(n \lg n)$  time.

- (b) **function** SET-INTERSECTION( $X, Y$ )  
     $\text{intersection} \leftarrow \text{EMPTY-SET}$   
     $\text{table} \leftarrow \text{HASH-TABLE}$   
    **for all** elements in  $X$  **do**  
        hash each element into  $\text{table}$   
    **end for**  
    **return** intersection  
**end function**
